Basic knowledge of disasters

Earthquake

The **intensity** of the **earthquake** depends on the **intensity of the shaking**, and it varies from place to place.

Magnitude is the magnitude of an earthquake.

It will only increase the magnitude a little, and it will be an unimarginably large earthquake.

When the magnitude increases by 1.0, **the energy of the earthquake** is 30 times, so a huge earthquake of

magnitude 8 has the energy of 30 earthquakes of

magnitude 7.

The seismic intensity is measured by an seismic intensity

meter as a measured seismic intensity. The Japan

Meteorological Agency announces the **seismic intensity**

of the seismic intensity meter installed by the Japan

Meteorological Agency and local governments.

The magnitude of the **earthquake** is affected not only by

the scale of the earthquake, but also by the distance from

the epicenter and ground characteristics.

When considering damage caused by an earthquake,

seismic intensity information is important.

Japan is a country with the most earthquakes in the world,

and there is a possibility of strong shaking anywhere in the

country.

On the other hand, it is difficult to predict that "a huge

earthquake will occur on △month△day" with current

scientific knowledge.

Meteorological Agency website.)

Tsunami

Tsunamis hit the coast near the epicenter immediately

after the earthquake.

The speed of the tsunami is determined by the depth of

the water. It is fast in the deep offshore and slow in the

shallows.

The first wave may already arrive before the **tsunami**

warning is announced.

As the water depth becomes shallower, **the height of the**

tsunami increases.

If an earthquake with a shallow epicenter and a magnitude

of 7 is more than 7, there is a risk of a **tsunami**.

The first wave of the tsunami is not the highest. **Tsunamis**

repeatedly rush in, and the second and third waves may be

the maximum. In addition, it may not only start with pull

waves, but also come with push waves. If you feel strong

shaking near the coast, **evacuate to a high ground**

immediately, and while a **tsunami warning** is announced,

it is important **not to approach lowlands** such as near the

coast.

Agency website.)

Torrential rain

In general, flooding caused by the collapse of the

embankment or the water of the river crossing the

embankment is called a **flood**.

Disasters caused by drainage that cannot keep up with the

increase in surface water due to heavy rain, etc.,

overflowing with drets and flooding, and obstruction of

drainage due to river surges and high tides, is called

flooding damage.

In urban areas, where the ground is covered with concrete

and asphalt, water is less likely to seep than soil, so water

enters the house, and water that has nowhere to go flows

to **subways** and **underground streets**. There is

something to do.

Landslide disaster

Landslide disasters such as **landslides, landslides, and**

landslides are mainly triggered by rain and earthquakes.

If the meteorological observatory announces a heavy rain

warning, pay attention to the subsequent information, and if

the meteorological observatory and prefecture jointly

announce the **landslide disaster warning information**, it

is important to take early action, such as evacuating

immediately.

If the following phenomena are seen, a landslide disaster

may occur immediately after. Immediately evacuate to a

safe place with the people around you and report it to the

relevant agencies.

- Mountains are ringing
- The flow of the river is swarm, and driftwood begins to mix
- Even though it continues to rain, the water level of the river is lowering
- Pebbles fall from the slope of the slope
- Water in streams and wells
- Cracks can be made on the ground
- Water gushes out of the slope
